

Based on the correlation heatmap, the features that most strongly influence house price are the total area, number of bathrooms, and whether the house has air conditioning. Between the two models, the Random Forest Regressor performed the best, explaining roughly 60–65% (0.6119) of the variance in house prices, compared to the Linear Regression model. One surprising insight from the data is that having a guestroom or being located near a main road had a significantly lower impact on the final price than basic square footage. Based on these findings, I recommend that the real estate business prioritize properties with larger areas and multiple bathrooms for their premium listings, as these are the most reliable indicators of a high market valuation.
